

## ABSTRACT

A braking control device for a vehicle executes braking force distribution (BFD) biased to ~~front wheel,~~ the front wheels, taking into account auxiliary braking control such as ~~Braking~~ braking assist control ~~to be~~ (BAS) executed when an abrupt or full braking action is ~~done~~ performed by the driver. In BFD ~~control,~~ control, a braking force ~~on~~ on the rear wheels is held at a holding braking force ~~and~~ and a braking force on the front wheels is incremented ~~beyond~~ beyond a braking force requested by a braking action ~~of a~~ of the driver. After the starting of BFD control, further increase in the braking action is reflected in the ~~front wheel~~ braking force. ~~When the~~ force of the front wheels. When auxiliary braking control is executed, the holding braking force on the rear wheels and the increment of the braking force on the front wheels are determined based upon a demand of the auxiliary braking action as well as the braking action amount by the driver.
